Any help will be appreciated. A: It seems like you have the logic wrong. I am guessing you need to first find the largest value in the vector and then find the smallest. In pseudo-code, the function you need would look like this: function find_the_smallest_and_largest(x) the_largest_value = max(x) the_smallest_value = min(x) return the_largest_value, the_smallest_value end function Once you have a pair of values, you can extract the corresponding values out of the vector using these functions: function get_the_smallest_value(x, y) return x[1] end function function get_the_largest_value(x, y) return x[2] end function That should get you started. Production of a monoclonal antibody-based enzyme-linked immunosorbent assay for the diagnosis of neurocysticercosis in Chile. Antibodies to neurocysticercosis are produced during the course of human infection. An enzyme-linked immunosorbent assay (ELISA) is used to detect these antibodies. The ELISA kit employed requires that eggs be used as antigenic source. We have developed a monoclonal antibody based ELISA that uses excretory/secretory antigens (ES antigens) as antigenic source to detect antibodies in serum. In this study, we evaluated a set of monoclonal antibodies to detect serum antibodies using ES antigens. We also evaluated the performance of the test by comparing the results with those obtained with a commercial kit. The results obtained using the monoclonal antibodies show that seven of the nine antibodies detected specific antibodies in the sera tested. The test had a sensitivity of 79% and a specificity of 86%. The immunoblotting technique confirmed that these antibodies were IgG antibodies.
